# THE MECHANISM OF THE ESTIMATION OF SUSTAINABLE DEVELOPMENT OF ENTERPRISES OF THE INDUSTRIAL COMPLEX 

#### Abstract

Theoretical and methodical bases of the mechanism of the estimation of sustainable development of the enterprises of an industrial complex are considered in the article. The offered mechanism of an estimation of sustainable development will allow estimating achievements of the enterprises and its divisions, the responsibility centres on one indicator synthesising all aspects of activity of the enterprise.

The domestic enterprises of an industrial complex show a wide spectrum of variants of the behaviour which are generally based on the aspiration to sustainable development. The experience of the organisations succeeding in conditions of the market convince that for their sustainable development is necessary a set of such properties as flexibility and speed of reaction to market condition changes, competitiveness of production and manufacture, investment activity, high liquidity and financial stability, wide use of innovative factors for selfdevelopment. The main point is how to provide the transition of the enterprise to a sustainable development in a combination to global processes.

In the scientific literature questions of sustainable development of the enterprises are considered widely enough. The main principles and approaches to the decision of the problems of sustainable development with reference to various branches and complexes are developed by A. G. Aganbegjanom, A. G. Granbergom, I. P. Smartly, V. A. Koptjugom, D. S. Lvovym, N. N. Nekrasov and others.

At the same time many questions remain unresolved in a domestic science, and the western experience demands careful reconsideration and the analysis and in the most cases does not correspond to conditions of transitive economy.

The analysis of the problem of stability of the industrial enterprise has shown that the research in this field is conducted intensively enough, but the attention of researchers is concentrated basically on its financial and economic aspects, though stability is a complex category which cannot be reflexion of only one aspect of activity of the enterprise.

The problem of an integrated estimation and maintenance of steady functioning of the industrial enterprises, especially in the conditions of globalisation of world economic communications are caused by the following reasons.

At first, the problem of maintenance of steady functioning of the enterprise is difficultly predicted, and danger of instability exists always, especially, if it is caused by the macroeconomic factors which are difficultly giving in to regulation from outside of the enterprise. Secondly, carrying out of an estimation of stability of functioning of industrial activity is necessary not only at the level of the enterprise, but also in the system of branch and regional development.

The conducted research of an estimation of sustainable development on an example of the industrial enterprise of Open Joint-stock Society "Pinema", allowed offering methodical recommendations about formation of a complex estimation of economic stability.

It is necessary to notice that the theme of the research in the conditions of globalisation of world ecenomic communications, economy transition to new market relations, of the increase of level of a competition on internal and foreign markets, necessity of maintenance of economic safety both the separate enterprise, and the state as a whole is actual and demands the further working out.

The interest of the participants of economic process to objective and trustworthy information about productivity of financial and economic activity of the enterprise essentially increases in the conditions of market economy. The paradigm of operation of the enterprise is
based on its perception, as a difficult system. The increase of quantity of objects of management and indicators of their estimation, leads to complication of problems of management, therefore it is expedient to estimate achievements of the enterprises and its divisions, the responsibility centers on one any indicator synthesising all aspects of activity of this object. However the inconsistency of allocation of any one productive indicators as the core from among generalising, is caused by complexity of industrial-economic activities. As a result the problems of an efficient control are reduced to the definition of a complex estimation of economic activities on the basis of a system of indicators with aggregation of various receptions of the qualitative and quantitative analysis.

The problem of formation of complex estimations of stability development of the industrial enterprises consists that generally the information about the enterprise characterises variety of the economic objects $\mathrm{OB}_{\mathrm{k}}$ presented by set of subobjects $\mathrm{SUB}_{\mathrm{r}}$ described by indicators $P_{i}$, each of them in its turn accepts value $N_{j}$ depending on set of factors $F_{m}$. It is necessary to notice that factors $\mathrm{F}_{\mathrm{m}}$ in dependence on level of their consideration at analysis are subdivided into factors of the first, the second and following usages. The choice of this or that order is defined by necessary depth of the economic analysis [11, p. 123]. The area of changes $k, i, j, r, m$ depends on concrete economic object (enterprise) (fig. 1).

Fig. 1. Representation of economic objects of the enterprise

The example of various objects $\left(\mathrm{OB}_{\mathrm{k}}\right)$, subobjects $\left(\mathrm{SUB}_{\mathrm{r}}\right)$ and indicators ( $\mathrm{P}_{\mathrm{i}}$ ), giving the information on productivity of financial and economic activity of the enterprise is resulted in table 1.

The quantity of indicators $P_{i}$ used at the enterprise can reach now some tens and even hundreds that it makes the analysis of financial and economic activity of the enterprise difficult enough [ 9, p. 107]. Therefore for the analysis it is expedient to generate one or several indicators synthesizing in almost all aspects of activity of enterprise [4].

Such indicators are reflected in a complex estimation (a summary indicator) J, representing the characteristic received as a result of simultaneous and coordinated studying of set of indicators $P_{i}$, depending on factors $F_{m}$.

By a complex estimation of efficiency of industrial-marketing and financial and economic activity of one enterprise can be compared with efficiency of activity of other enterprises. Various methods, such as the sums of places, distances, a target estimation, etc. [8] are used for formation of a complex estimation.

Along with advantages of the specified methods, there is a number of lacks:

- the choice of concrete indicators from all their set $P_{i}$ for formation of a complex estimation is not proved;
- the choice of weight factors of indicators is not proved at calculation of a complex estimation;
- the choice of final function of calculation of a complex estimation is not proved;
- the analysis of influence of factors $\mathrm{F}_{\mathrm{m}}$ on dynamics of complex estimation J is not carried out.

Table 1
Objects, subobjects and indicators

| Objects $\left(O B_{k}\right)$ | Subobjects $\left(S U B_{r}\right)$ | Indicators $\left(P_{i}\right)$ |
| :--- | :--- | :--- |
| The basic <br> means | The basic means of a <br> principal view of activity, <br> active part of the basic <br> means, the equipment | Validity factor, updating factor, fundefficiency, <br> fundprofitability, fundequipment |
| Labour force | The enterprise personnel, <br> the personnel of a principal <br> view of activity, workers | Numbers, working hours fund, average development of <br> the worker, profitability of the personnel |
| Payment | Kinds of payments from a <br> wages fund, a wages fund <br> on categories of workers | The sum of payments from a wages fund by kinds, an <br> average wages, factor of an advancing of rates of <br> increase of labour productivity over rates of increase of <br> wages, profit on wages fund rouble |
| Material <br> resources | Kinds of materials, <br> material expenses | Factor of rhythm of receipt of materials, <br> materialcapacity, materialefficiency |
| Pxpenses <br> expenctuss, articles of <br> expconder articles of <br> elements and economic | The product cost price, the sum under separate articles of <br> expenses, expensescapacity |  |
| Release and <br> realisation of <br> products | Kinds of released products | Volume of release and production realisation, factor of <br> rhythm of output, level of realisation of production |
| Money <br> resources | Articles of receipt and <br> the expense of money <br> resources | Positive, negative and pure monetary stream, <br> profitability of a pure monetary stream, turn over <br> money resources |
| Taxes | Types of taxes | The general level of tax loading, level of tax loading on <br> the cost price, a gain, profit |
| Financial <br> results | Kinds of products <br> profit from product realisation, profitability of expenses, <br> profility of sales |  |
| Financial <br> condition | Solvency of the enterprise, <br> financial stability of the <br> enterprise | Factor of current liquidity, factor of provision with own <br> circulating assets, factor of financial independence |

For elimination of the specified lacks we will use available author's approaches to an estimation of productivity of financial and economic activity of the enterprise [8, p. 11]. So, it is offered two models of formation of complex estimations of economic stability of the enterprise, which results mutually supplement each other.

The first model can be used for formation of a complex estimation of the enterprises as a whole, and its separate divisions or objects $\mathrm{OB}_{\mathrm{K}}$, and it does not dependent on a branch accessory of the enterprise.

The second model is applicable only for the enterprise as a whole, thus it depends on its branch accessory (the industry, agriculture, trade, building etc.).

Let's consider methodical bases of a complex estimation of economic stability on offered models.

The first model of formation of a complex estimation of economic stability provides the following stages:

- formation of indicating spaces $\mathrm{P}^{`}$ indicators $\mathrm{P}_{\mathrm{i}}, \mathrm{P}_{\mathrm{i}} € \mathrm{P}$ `; - formation of reduced indicating spaces \(\mathrm{P}^{`}{ }_{\text {red }}, \mathrm{P}^{`}\) red \(€ \mathrm{P}{ }^{`}\);
- formation of normalized reduced space $\mathrm{P}^{`}{ }_{\text {norm }}, \mathrm{P}^{`}{ }_{\text {norm }} \sim \mathrm{P}^{`}{ }_{\text {red }}, \mathrm{P}_{\text {norm i }} \sim \mathrm{P}_{\mathrm{i}}$;
- definition of factors of importance $K_{i}$ of indicators $P_{\text {norm }}$;
- calculation of complex estimation $\mathrm{J}_{1}$ (fig. 2).

At the first stage there is a formation of indicating spaces $\mathrm{P}^{`}$, i.e. formation of system of indicators $P_{i}$ characterising all aspects of activity of the enterprise and calculation of their values $\mathrm{N}_{\mathrm{i}}$ in the necessary historical period (days, months, quarters, years) in the form of a database. The greatest possible quantity of indicators $P_{i}$ which characterise such objects $\mathrm{OB}_{\mathrm{K}}$, as the basic means, a labour force, a payment, material resources, expenses, release and production realisation, taxes, money resources, financial results, a financial condition, etc. [4, 5, 6] is thus used.

Fig. 2. The first model formation of a complex estimation

At the second stage it is formed reduced indicating space $\mathrm{P}{ }^{\text {red }}, \mathrm{P}{ }^{\text {red }} € \mathrm{P}$ ` i.e. those indicators which most informatively describe aspects of activity of the enterprise interesting an analyst are selected. Selection occurs with methods of the natural, artificial and combined intelligence, and also statistical methods and mathematical programming [2, 3, 10] (fig. 3).

Using methods of pair correlation factors of pair correlation $\mathrm{r}_{\mathrm{ij}}$ indicators $\mathrm{P}_{\mathrm{i}}$, for example, pay off the factors of pair correlation $\mathrm{r}_{\mathrm{ij}}$ indicators $\mathrm{P}_{\mathrm{i}}$ and their some threshold value $\tau$ is set. According to a scale of Cheddoka it is more expedient to use value $\tau=0,3$ [8]. From the further consideration those indicators $P_{i}$, for which it is carried out $r_{i j}>\tau$ are excluded and for everyone $r_{i j}$ the expert chooses the most important indicator from the remained indicators on its point of view. Thus, a number of indicators $\mathrm{P}_{\mathrm{i}}$, which are almost independent from each other and form reduced indicating space $\mathrm{P}^{`}$ red, is left . It is necessary to notice that at small number of indicators $\mathrm{P}_{\mathrm{i}}$ and a rather small amount of objects $\mathrm{OB}_{\mathrm{k}}$ experts usually successfully form reduced indicating space $\mathrm{P}_{\text {red }}{ }^{\text {. }}$ At increase of quantity of objects $\mathrm{OB}_{\mathrm{K}}$ and especially indicators $\mathrm{P}_{\mathrm{i}}$ the decision of the problem, however, considerably becomes complicated [2, 8, 10].

At the third stage formation of normalized reduced space $\mathrm{P}{ }^{`}$ norm is carryed out. Rationing allows to lead to a uniform scale such diverse indicators $P_{i}$ as, for example, validity factor, middle age of the equipment advanced in years, fundprofitability in percentage and
fundefficiency in millions roubles etc. Thus before rationing it is expedient to apply the rule «of three sigm» to dispose of the casual values $\mathrm{P}_{\mathrm{i}}$, belonging $\mathrm{P}^{`}$ norm.

Fig. 3. Methods of a reduction of space of indicators

It is standard in the mathematician to result different sizes in a dimensionless (standard) interval [ $0 ; 1$ ], and models of linear, nonlinear, statistical rationing [12] can be used for rationing. The linear model, where direct and return rationing is applied in dependence on an orientation of dynamics of indicators, is more often used.

Direct rationing is applied in a case when growth of indicator is considered as the positive tendency:

$$
\begin{equation*}
\mathrm{P}_{\text {norm } \mathrm{i}}=\left(\mathrm{P}_{\mathrm{i}}-\mathrm{P}_{\min }\right) /\left(\mathrm{P}_{\max }-\mathrm{P}_{\min }\right), \tag{1}
\end{equation*}
$$

where $\mathrm{P}_{\text {norm }} \mathrm{i}^{-}$normalized value of indicator $\mathrm{P}_{\mathrm{i}} ; \mathrm{P}_{\text {min }}$ - the minimum value of indicator $\mathrm{P}_{\mathrm{i}}$; $P_{\text {max }}$ - the maximum value $P_{i}$.

Return rationing is used in a case when the positive tendency is indicator decrease:

$$
\begin{equation*}
\mathrm{P}_{\text {norm }} \mathrm{i}=\left(\mathrm{P}_{\max }-\mathrm{P}_{\mathrm{i}}\right) /\left(\mathrm{P}_{\max }-\mathrm{P}_{\min }\right), \tag{2}
\end{equation*}
$$

After rationing the table with normalized values $\mathrm{P}_{\text {norm }}$ [8] is made.
At the fourth stage factors of importance $\mathrm{K}_{\mathrm{i}}$ of indicators $\mathrm{P}_{\mathrm{norm}} \mathrm{i}$, and also a vector of priorities V by means of a method of pair comparisons of Saati [7] are defined.

Generally importance factors can be defined also by methods of Fishberna, family of methods Promethee, family of methods Electre, etc. [1].

At the fifth stage calculation of complex estimation $\mathrm{J}_{1}$ is made. For calculation function of convolution [12], which gets out in dependence on interchangeability and complementarity of indicators, degree of disorder of their values, is used.

It is obvious that values $J_{1}$ are in the range from 0 to 1 , that facilitates visual representation of its change in time. Besides it is offered to break area of change $\mathrm{J}_{1}$ on some equal intervals, to each of which there corresponds a verbal estimation (table 2).

Table 2
Verbal estimations of intervals of change $\mathbf{J}_{1}$

| Change interval | Verbal estimation |
| :--- | :--- |
| $[0 ; 0,25)$ | Unsatisfactory situation |
| $[0,25 ; 0,5)$ | Satisfactory situation |
| $[0,5 ; 0,75)$ | Good situation |
| $[0,75 ; 1]$ | Excellent situation |

Dynamics of complex estimation $\mathrm{J}_{1}$ in time can be presented in the form of the schedule. It is necessary to notice that the first model formation of complex estimation $J_{1}$ can effectively be used as for the separate division as for the enterprise as a whole. Besides it allows to estimate separate objects $\mathrm{OB}_{\mathrm{K}}$.

Let's make calculations of a complex estimation financially - economic activities of the industrial enterprise on the basis of the first model for which estimation are used over 170 indicators.

1st stage. It is formed indicating space $\mathrm{P}^{`}$, consisting of 120 most important indicators of activity of the enterprise for 12 months.

2nd stage. The reduced space of indicators $\mathrm{P}^{`}$ red, $\mathrm{P}^{`}$ red $€ \mathrm{P}^{`}$ is defined by drawing up of a matrix of pair correlations of dimension $120 \times 120$. Factors of pair correlation $r_{i j}$ indicators $P_{i}$ pay off and their threshold value $\tau=0,3$ is set. As a result 5 independent indicators (table 3 ) are allocated.

Table 3
Actual values of indicators of reduct for calculation of a complex estimation
of activity of the enterprise during the investigated period

| Indicators | Months of the accounting period |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| Factor of an advancing of rates of increase of labour productivity over rates of increase of wages (Fap) | 1,045 | 0,916 | 1,137 | 1,026 | 0,936 | 1,049 | 1,050 | 0,955 | 0,983 | 1,023 | 0,972 | 0,976 |
| Factor of provision with own circulating assets(Foca) | 0,4966 | 0,4966 | 0,4966 | 0,4869 | 0,4869 | 0,4869 | 0,4977 | 0,4977 | 0,4977 | 0,4774 | 0,4774 | 0,4774 |
| Rate of increase of profit (loss) from production realisation (works, services) (Rpr) | 0,3396 | 1,2844 | 0,8071 | 1,2655 | 0,9580 | 0,4672 | 0,6406 | 1,1951 | 0,9184 | 0,2222 | 8,7000 | 1,4943 |
| Rate of increase of profit of the accounting period (Rpap) | 0,1478 | 1,5536 | 0,6667 | 1,9138 | 0,9369 | 0,3077 | 1,7188 | 1,1455 | 0,9048 | 2,7544 | 0,3758 | 0,3051 |
| Factor of turnover of debtor's debts (Ft) | 0,4697 | 0,3768 | 0,5568 | 0,4356 | 0,5023 | 0,4391 | 0,4043 | 0,4376 | 0,4860 | 0,5171 | 0,5540 | 0,4983 |

3rd stage. Rationing of indicators of reduct is done according to formulas 1 and 2 which results are presented in table 4.

Table 4
Normalized values of indicators of reduct for calculation of a complex estimation of activity of the enterprise during the investigated period

| Indicators | Months of the accounting period |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| Factor of an advancing of rates of increase of labour productivity over rates of increase of wages (Fap) | 0,489 | 0,000 | 0,837 | 0,415 | 0,073 | 0,501 | 0,506 | 0,146 | 0,253 | 0,403 | 0,210 | 0,225 |
| Factor of provision with own circulating assets(Foca) | 0,132 | 0,132 | 0,132 | 0,066 | 0,066 | 0,066 | 0,140 | 0,140 | 0,140 | 0,000 | 0,000 | 0,000 |
| Rate of increase of profit (loss) from production realisation (works, services) (Rpr) | 0,887 | 0,979 | 0,933 | 0,978 | 0,947 | 0,899 | 0,916 | 0,971 | 0,944 | 0,875 | 0,000 | 1,000 |
| Rate of increase of profit of the accounting period (Rpap) | 0,000 | 0,539 | 0,199 | 0,678 | 0,303 | 0,061 | 0,603 | 0,383 | 0,290 | 1,000 | 0,087 | 0,060 |
| Factor of turnover of debtor's debts (Ft) | 0,544 | 0,526 | 0,562 | 0,538 | 0,551 | 0,538 | 0,531 | 0,538 | 0,548 | 0,554 | 0,561 | 0,550 |

4th stage. Definition of factors of the importance of indicators of reduct (table 5).
Table 5
Definition of factor of the importance with use of a method of the analysis of hierarchies of Saati

|  | Fap | Foca | Rpr | Rpap | Ft | Average geometrical | Importance factor | Vector of priorities |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Fap | 1 | 3 | 0,5 | 0,5 | 0,5 | 0,822 | 0,162 | 5 |
| Foca | 0,333 | 1 | 4 | 6 | 0,5 | 1,319 | 0,260 | 1 |
| Rpr | 2 | 0,25 | 1 | 0,5 | 2 | 0,871 | 0,172 | 4 |
| Rpap | 2 | 0,167 | 2 | 1 | 2 | 1,060 | 0,209 | 2 |
| Ft | 2 | 2 | 0,5 | 0,5 | 1 | 1,000 | 0,197 | 3 |
| The sum |  |  |  |  |  |  |  |  |

5th stage. Calculation of a complex estimation is done with the help additive function of convolution (the formula 3):

$$
\begin{equation*}
J_{1}=\sum_{\mathrm{i}=1} \mathrm{~K}_{\mathrm{i}} \cdot \mathrm{P}_{\mathrm{norm} \mathrm{i}} \tag{3}
\end{equation*}
$$

Graphic representation of results of calculation is shown on fig. 4.
It is necessary to notice that the analysis of influence of separate factors $\mathrm{F}_{\mathrm{m}}$ on the general complex estimation J in some cases is interesting. It is necessary to notice that the first model, offered above, allows estimating influence of factors of the first order. Besides the first model complicates carrying out of the factorial analysis, in which used the results of the pair correlation, defining various indicators $\mathrm{P}_{\mathrm{i}}$ in various situations.

The second model of formation of complex estimation J is offered for elimination of lacks and more profound analysis.

The factorial analysis put in a basis of construction of the second model, thus indicators $P_{i}$ represent itself as factors of the first order.

Fig. 4. Graphic representation of results of calculation of complex estimation $\mathrm{J}_{1}$

The second model of formation of a complex estimation of economic stability provides the following stages (fig 5):

- choice of objects depending on a branch accessory and a kind of activity of the enterprise;
- definition of indicator $\mathrm{P}_{\mathrm{i}}$ for each chosen object $\mathrm{OB}_{\mathrm{K}}$;
- rationing of indicators $\mathrm{P}_{\text {norm }} \sim \mathrm{P}_{\mathrm{i}}$;
- definition of factors of importance $K_{i}$ for indicators $P_{\text {norm }}$;
- calculation of complex estimation $\mathrm{J}_{2} \$$
- definition of a quantity of usages of factorial model for each indicator $P_{i}$;
- the analysis of influence of factors $F_{i}$ on dynamics of a complex estimation.

Fig. 5. The second model of formation of a complex estimation

At the first stage the branch accessory and a kind of activity of the enterprise is defined. On the basis of it the objects of the economic analysis get out. It is possible to present the results of a choice in the form of tables (table 6).

Table 6
Choice of objects

| Objects $(O B \kappa)$ |  | Kinds of activity |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Industry | Trade | Transport | Agriculture | Building | Catering | etc. |
| Labour force | + | + | + | + | + | + |  |
| Payment | + | + | + | + | + | + |  |
| Material resources | + | - | + | - | - | - |  |
| The basic means | + | + | + | + | + | + |  |
| Expenses | + | + | + | + | + | + |  |
| Money resources | + | + | + | + | + | + |  |
| Calculations | + | + | + | + | + | + |  |
| The production program | + | - | - | + | - | - |  |
| Marketing activity | + | + | + | + | + | + |  |
| Financial results | + | + | + | + | + | + |  |
| Financial condition | + | + | + | + | + | + |  |
| Goods turnover | - | + | - | - | - | + |  |
| Commodity stocks | - | + | - | - | - | + |  |
| Distribution costs | - | + | - | - | - | + |  |
| Turnover of goods | - | - | + | - | - | - |  |
| Passenger turnover | - | - | + | - | - | - |  |
| Quantity of executed works | - | - | - | - | + | - |  |
| Complex estimations | + | + | + | + | + | + |  |

At the second stage indicator $\mathrm{P}_{\mathrm{i}}$ for every $\mathrm{OB}_{\mathrm{K}}$ is defined As a rule the standard indicators of efficiency get out. For example, for the industrial enterprise for object "labour force" the indicator «average development of the worker» gets out, for object «the basic means» the indicator «fundefficiency» gets out, etc.

At the third stage rationing of indicators $\mathrm{P}_{\text {norm }} \sim \mathrm{P}_{\mathrm{i}}$ is made, it is similar to the first model.
At the fourth stage factors of importance $K_{i}$ of indicators $\mathrm{P}_{\text {norm }} \mathrm{i}$, are defined by methods of expert estimations as it is specified in the first model. For the second model, however, it is recommended to expand a quantity of experts for reception of more authentic result (up to 10 experts).

At the fifth stage calculation of complex estimation $\mathrm{J}_{2} \mathrm{c}$ is carried out by use of function of convolution. Unlike the first model, where there is freedom in a choice of a kind of function of convolution, in the second model it is offered to use additive function:

$$
\begin{equation*}
J_{2}=\sum_{\mathrm{i}=1} \mathrm{~K}_{\mathrm{i}} \cdot \mathrm{P}_{\text {norm } \mathrm{i}} \tag{4}
\end{equation*}
$$

Additive function of convolution will allow to carry out the analysis of influence of factors on dynamics of a complex estimation under the most simple scheme.

At the sixth stage the order of factorial model is defined. The quantity of usages of factorial model can be much. It is offered to be limited to the first and second order, thus for factors of the first order to use the additive model coinciding with additive function of convolution, for factors of the second order - multiplicate model.

At the seventh stage the analysis of influence of factors on dynamics of a complex estimation is carried out. The analysis of estimation change $\Delta \mathbf{J}_{2}^{p i}$ is done under each factor $\mathrm{P}_{\mathrm{i}}$ separately. For the first order:

$$
\begin{equation*}
\Delta J_{2}^{p i}=\mathrm{K}_{\mathrm{i}} \cdot \Delta P_{n o r m \mathrm{i}} . \tag{5}
\end{equation*}
$$

For the second order:

$$
\begin{gather*}
P_{i}=\prod_{m=1} F_{m}  \tag{6}\\
\Delta \mathrm{~J}_{2}^{p i}=\mathrm{K}_{\mathrm{i}} \cdot \Delta P_{n o r m \mathrm{i}}=K_{i} \cdot \sum_{i=1} \Delta P_{n o r m \mathrm{i}}^{\mathrm{F}} \tag{7}
\end{gather*}
$$

where $\Delta P_{\text {norm } \mathrm{i}}^{\mathrm{F}}$ - change of indicator $\mathrm{P}_{\text {norm } \mathrm{i}}$ at the expense of factor $\mathrm{F}_{\mathrm{m}}$.

As multiplicate model (6) does not assume rationing of indicators and factors, and change $\Delta \mathbf{J}_{2}^{p i}$ (7) contains normalized values $\mathrm{P}_{\text {norm }}$, it is necessary to enter the factor of recalculation $K_{i}^{\prime \prime}$ :

$$
\begin{equation*}
K_{i}^{\prime \prime}=\frac{\Delta P_{n o r m \mathrm{i}}^{\mathrm{F}}}{\Delta P_{\mathrm{i}}^{\mathrm{F}}} \tag{8}
\end{equation*}
$$

Thus, change of complex estimation $\Delta J_{2}^{\mathrm{F}}$ norm in dependence on change of factors $F_{m}$ :

$$
\begin{equation*}
\Delta J_{2 \text { norm i }}^{\mathrm{F}}=K_{i} \cdot \sum_{i=1} K_{i}^{\prime \prime} \cdot \Delta P_{i}^{F} . \tag{9}
\end{equation*}
$$

For an estimation of influence of factor $\mathrm{F}_{\mathrm{m}}$ on dynamics of complex estimation $\mathrm{J}_{2}$ for the investigated period it is necessary to find its absolute change. The most progressive approach is offered in work [11]. Namely, application of decomposition of a pure gain of the factor by an integrated method of the factorial analysis to a time sign which consists that indicator change for the investigated period (we will tell a year), it is not a difference between accounting and base value, and the sum of dynamics of indicators for each subperiod.

$$
\begin{equation*}
\Delta P_{i}^{F}=K_{i}^{\prime \prime} \cdot \ln \left(\frac{F_{m 1}}{F_{m 0}}\right), \tag{10}
\end{equation*}
$$

where $\mathrm{F}_{\mathrm{m} 1}, \mathrm{~F}_{\mathrm{m} 0}$ - values of factors in the accounting and base subperiods.

$$
\begin{equation*}
K=\frac{\Delta P_{i}}{\ln \left(P_{i 1} / P_{i 0}\right)} \tag{11}
\end{equation*}
$$

where $\mathrm{P}_{\mathrm{i} 1}, \mathrm{P}_{\mathrm{i} 0}$ - values of factors in the accounting and base subperiods.
Let's make for the specified industrial enterprise calculations of a complex estimation of economic stability of the enterprise by using the second model.

Let's formulate algorithm of calculation of the given complex estimation, having broken it into seven consecutive stages.

1st and 2nd stages are a choice of objects depending on a branch accessory and a kind of activity of the enterprise and definition of indicator $\mathrm{P}_{\mathrm{i}}$. As in the conditions of an example it is necessary to calculate a complex estimation for the industrial enterprise, so according to table 6 we choose objects and corresponding indicators (table 7).

Table 7
Objects of the analysis of financial and economic activity of the enterprise and indicators, corresponding to them

| Object of the analysis $\left(\mathrm{OB}_{k}\right)$ | The chosen indicator $\left(P_{i}\right)$ | Conditional designation <br> of an indicator |
| :--- | :--- | :---: |
| 1. The basic means | Fundefficiency | FE |
| 2. Labour force | Annual development of the worker | AD |
| 3. Payment | Profitability of wages | Pw |
| 4. Material resources | Materialcapacity | Mc |
| 5. Expenses | Expensescapasity | Ec |
| 6. Release and production realisation | The level of realisation | Lr |
| 7. Money resources | Profitability of money resources | Pmr |
| 8. Taxes | Level of the general tax loading | Ltax |
| 9. Financial results | Profitability of sales | Ps |
| 10. A financial condition | Factor own circulating assets | Foca |

3rd stage. It is necessary to carry out rationing of the chosen indicators (table 8) on the basis of their actual values for 12 months (table 9).

Table 8

Having performed similar operations by 9 experts, we have received the following matrix $10 \times 10$, presented in table 11. The following workers of the enterprise of Open Joint-stock Society "Pinema" acted as experts : the assistant to the general director on economy, chief of economical department, the leading economist, the chief accountant, the assistant to the chief accountant, the leading bookkeeper, the leading engineer on the organisation and work rationing, chief of work and wages department, leading expert of marketing and sale department. Further by using a median of Kemeni [7, p. 18] we will spend processing of results of a group choice of experts for reception of resultants of factors of importance $K_{i}$ (a common opinion of expert group).

Table 11
Opinion of experts on the importance of the indicators used for calculation of a complex estimation

Stage 6. It is offered to limit definition of quantity of usages of factorial model to two. For productive indicator $J_{2}$ indicators $P_{i}$ will act as factors of the first order, each of which characterises efficiency of use of object $\mathrm{OB}_{\mathrm{K}}$. Further by using a method of expansion (tab. 13) we will define factors of the second order.

Table 13
Definition of models of the first order and factors of the second order for carrying out the factorial analysis of a complex estimation

| The calculation formula | Entered indicator | Expansion model |
| :---: | :---: | :---: |
| FE=OP/BM, where OP - output; BM - midannual cost of the basic means of a principal view of activity | BMa - an active part of midannual cost of the basic means of a principal view of activity | $\mathrm{FE}=\mathrm{OP} / \mathrm{BM}=\mathrm{BMa} / \mathrm{OP} \times \mathrm{OP} / \mathrm{BMa}=\mathrm{RDa} \times \mathrm{FEa}$, where RDa - relative density of an active part of the basic means of a principal view of activity in a total sum; FEa - fundefficiency an active part of the basic means of a principal view of activity |
| AOP =OP/ANW, where OP - output; ANW - average number of workers of a principal view of activity | ANWw average number of workers of a principal view of activity | AOP $=$ OP/ANW $=A N W w / A N W \times O P / A N W w=R D w \times$ AOPw, <br> where RDw-relative density of working workers <br> in an aggregate number; AOPw - mid-annual development of the worker |
| $\mathrm{Pw}=\mathrm{Pr} / \mathrm{FW}$, where Pr profit on realisation of production, works, services; FW - a wages fund of workers of a principal view of activity | FWw - a wages fund of workers of a principal view of activity | $\mathrm{Pw}=\mathrm{Pr} / \mathrm{FW}=\mathrm{FW} / \mathrm{FW} \times \mathrm{Pr} / \mathrm{FWw}=\mathrm{RDw} \times \mathrm{Pww}$, where RDw - relative density of a wages fund of workers in a total sum of a wages fund of workers of a principal view of activity; Pww - profitability of wages of the worker |
| $\mathrm{Mc}=\mathrm{MI} / \mathrm{OP}$, where Mc - material inputs; OP output | MId - direct material inputs | $\mathrm{Mc}=\mathrm{MI} / \mathrm{OP}=\mathrm{MI} / \mathrm{MId} \times \mathrm{MId} / \mathrm{OP}=$ Fpar mi $\times$ Mcd, where Fpar mi - factor of a parity of all and direct material inputs; Mcd - materialcapacity of direct material inputs |
| Ec=CP/OP, where CP - the full cost price of let out production; OP - output | CPi - the industrial cost price of let out production | Ec=CP/OP=CP/CPi $\times$ CPi/OP=Fpar cp×Eci, where Fpar cp - factor of a parity of the full and industrial cost price of let out production; Eci - expensescapacity of production |

Table 13

| The calculation formula | Entered indicator | Expansion model |
| :---: | :---: | :---: |
| Lr=G/OP, where G-a gain from realisation of production, works, services; OP - output | CPr - the full cost price of realised production | $\mathrm{Lr}=\mathrm{G} / \mathrm{OP}=\mathrm{G} / \mathrm{CPr} \times \mathrm{CPr} / \mathrm{OP}=\text { Fpar } \mathrm{g} \times \mathrm{Ec} \mathrm{r},$ <br> where Fpar $g$ - factor of a parity of a gain from realisation of production, works, services to its full cost price; Ec r-expensescapacity of realised production |
| $\mathrm{Pmr}=\mathrm{Pr} / \mathrm{MR}$, where Pr profit on realisation of production, works, services; MR - a total sum of money resources | MRr - receipt of money resources (a positive monetary stream) | $\mathrm{Pmr}=\mathrm{Pr} / \mathrm{MR}=\mathrm{MRr} / \mathrm{MR} \times \mathrm{Pr} / \mathrm{MRr}=\mathrm{Da} \times \mathrm{Pa},$ <br> where Da - a share of the arrived money resources in their general <br> sum; Pa - profitability of the arrived money resources |
| Ltax $=\mathrm{Tt} / \mathrm{G}$, where $\mathrm{Tt}-\mathrm{a}$ total sum of the taxes paid by the enterprise; the G-gain | Tg - the sum of the taxes paid by the enterprise from a gain | $\operatorname{Ltax}=\mathrm{Tg} / \mathrm{G}=\mathrm{Tt} / \mathrm{Tg} * \mathrm{Tg} / \mathrm{G}=$ Fpar $\mathrm{t} * \mathrm{Ltg}$, <br> where Fpar $t$ - factor of a parity of a total sum of taxes to the sum of the taxes paid from a gain; Ltg - level of tax loading on a gain |
| $\mathrm{Ps}=\mathrm{Pr} / \mathrm{Gr}$, where Ps profit on realisation of production, works, services; Gr - a gain from realisation of production, works, services | CPr - the full cost price of realised production | $\mathrm{Ps}=\mathrm{Pr} / \mathrm{Gr}=\mathrm{CPr} / \mathrm{G} \times \operatorname{Pr} / \mathrm{CPr}=\mathrm{De} \times \mathrm{PEr}$, where $\mathrm{De}-$ a share of expenses for realisation in a gain from realisation of production, works, services; PEr - profitability of expenses realised production, works, services |
| Foca $=O C A / T A$, where OCA - own circulating assets; TA - turnaround actives of the enterprise | Ma-material actives of the enterprise | Foca $=O C A / T A=O C A / M a \times M a / T A=D m a \times F t$ oca ma, where Dma - a share of material turnaround actives of the enterprise in a total sum of turnaround actives; Ft oca ma - factor of security of material turnaround actives own circulating assets |

The structurally-logic model of the analysis of complex estimation $J_{2}$ is presented on fig. 6.

Fig. 6. Structurally-logic model of the analysis of complex estimation $\mathrm{J}_{2}$

Stage 7. The factorial analysis of a complex estimation. Calculation of influence of factors of the first and second usages with use of methods of absolute differences and integrated [5, p. 89] according to formulas 5-9 is carried out. Results of such analysis for one of months (February of a base year) are presented in table 14.

Table 14.
The analysis of influence of factors of 1-st and 2-nd order on dynamics of a complex estimation of financial and economic activity of the enterprise for the investigated period

For an estimation of adequacy of the offered models comparison of results of calculation $\mathrm{J}_{1}$ and $\mathrm{J}_{2}$ is spent.

Apparently, the results on the first and second model slightly disperse, affinity of the results (factor of correlation 0,7 ) allows to draw a conclusion about reliability of the received results that in turn allows to draw a conclusion on adequacy of the offered models for an estimation of stability of the enterprise (fig. 7).

Fig. 7. Graphic representation of the results of calculation of complex estimations

The considered models of formation of a complex estimation of economic stability of the enterprise in our opinion are universal and can be applied at the enterprises of various patterns of ownership. Besides, they eliminate such lacks, as groundlessness of a choice of concrete indicators, their weight factors, and verification function. Thus the first model can be used for formation of a complex estimation of the enterprises as a whole, and its separate divisions or
objects, and it does not dependent on a branch accessory of the enterprise. The second model is applicable only for the enterprise as a whole, thus it depends on its branch accessory (the industry, agriculture, trade, building, etc.). Thus, the offered mechanism of an estimation of a sustainable development will allow estimating achievements of the enterprises and its divisions, the responsibility centres on one indicator synthesising all aspects of activity of the enterprise that will lead to well-founded administrative decisions at the enterprise.
